Diaphragm Strain Gauges for Pressure Sensors and Force Transducers

Description

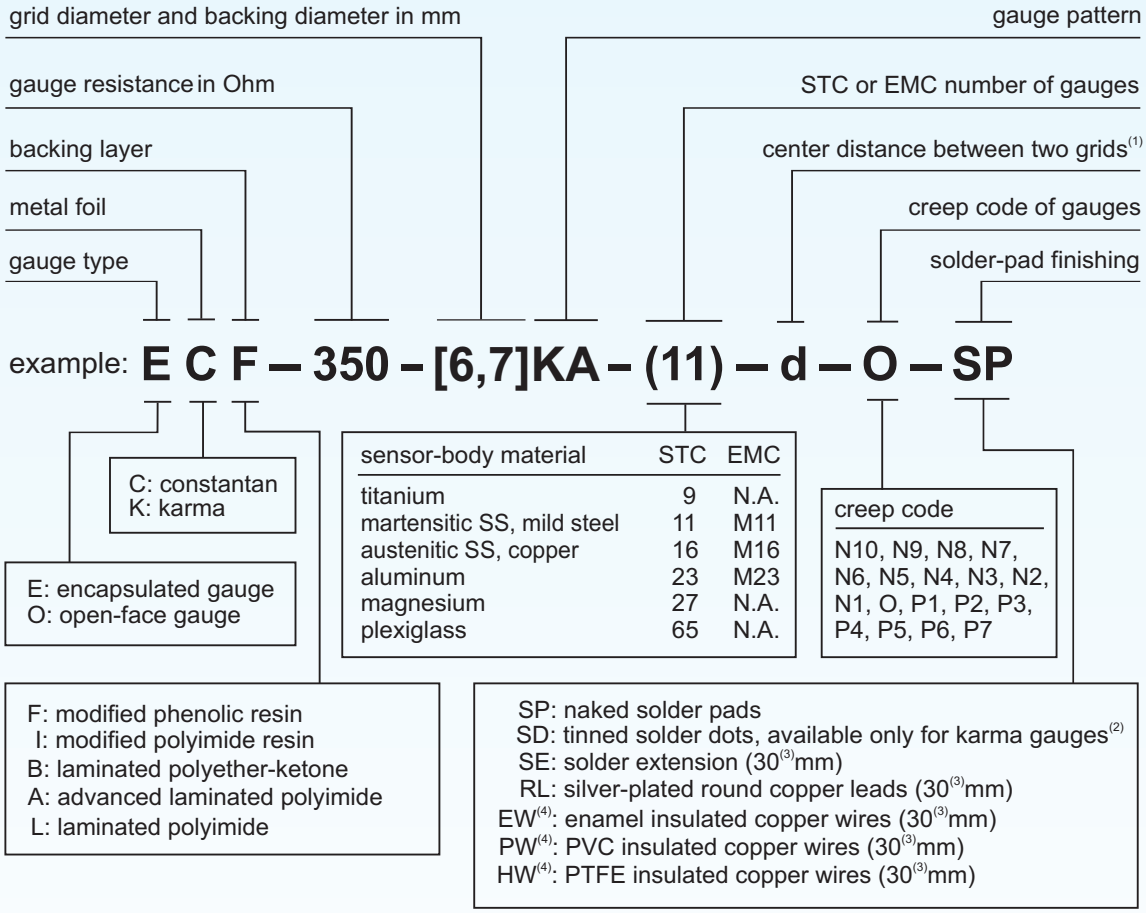
BCM SENSOR diaphragm KA-series strain gauges are specially developed for manufacturing precision pressure sensors, while the KC-series strain gauge are for manufacturing precision force transducers. For the purpose of the specific application, the full-bridge strain gauges are temperature and creep compensated, and they can be either encapsulated or open-face according to the requirement.

The karma gauges can be manufactured with effective modulus compensation (EMC). The EMC gauges are mostly for manufacturing low-cost force transducers, because with the EMC gauges the manufacturers can eliminate the use of compensation resistors and achieve the sensitivity compensation.

For creep compensation, there are 18 creep codes: “N10, N9, N8, ..., O, ..., P5, P6, P7". The “N10” is the most negative creep code, while the “P7" is the most positive one. The “O” stands for a moderate creep code. For a specific strain gauge, please find its available creep code below its dimensions at the “Option *9" on the following pages. For a customized creep code, consult BCM SENSOR.

For more information on self-temperature compensation (STC), creep compensation, and EMC of strain gauges, please refer to the corresponding articles respectively on the website of BCM SENSOR.

Ordering Information



Notes: (1) This code is only applicable to either the half- or full-bridge SG.

(2) It is recommended to select this option, if one wants to use the karma gauges and has no any experience having soldered leads or wires onto the karma gauges.

(3) 30mm is a standard length. The customized length is available on request.

(4) Working temperature ranges of the wires:
EW: -40 ~ +150°C; PW: -40 ~ +105°C; HW: -80 ~ +250°C.

Notes:

(*): The tolerance and dispersion of the gauge resistance is influenced by both the level of resistance and the gauge pattern. The specific tolerance and dispersion can be found in Selection Chart for the specific gauge pattern of metal foil strain gauges (SG).

(**): The fatigue life of metal foil SG was tested by tensile strain. The number of cycles of fatigue life of metal foil SG was tested and obtained when the tensile strain level was set at 1000με. The lower the tested strain level, the more cycles or longer fatigue life of the metal foil SG under test. When the tested strain level is lower than 200με, the metal foil SG under test may have much longer fatigue life.

(***): The available creep codes can be found in Selection Chart for the specific gauge pattern of metal foil SG.

(****): The maximum working current of SG is determined by the heat dissipation of SG. The heat dissipation of SG depends on the quality of bonding process (gluing and curing), the quality of sensor body material, and profile of the sensor body. For a given SG resistance, the maximum excitation voltage of sensors is determined by the maximum working current of the SG. If there is a sufficient heat dissipation channel underneath the SG, the maximum excitation voltage may be set to 12Vdc crossing the Wheatstone bridge circuit of the SG of 350Ω resistance, to keep the working temperature of the Wheatstone bridge circuit within the compensated temperature range of the sensor. Nevertheless, if the heat dissipation channel is not sufficient to dissipate the heat, due to the limit of dimension or profile of sensor body, the heat which is created by the working current may cause a localized increase of temperature in the Wheatstone bridge circuit. To keep the working temperature of the Wheatstone bridge circuit within the compensated temperature range of the sensor, it is recommended to lower the maximum excitation voltage e.g., not higher than 10Vdc crossing the Wheatstone bridge circuit of the SG of 350Ω resistance.

Notes: (1) Lower resistances are available for large-volume orders.
(2) Other creep codes are available for large-volume orders.
(3) Only necessary to select if one wants to use the karma gauges.
